NEW BOND PRICING METHOLODOLGY

Methodology

The methodology designed in the bond pricing model is based on discounting each cash flow using the zero or spot rate associated with the tenor of that cash flow. The methodology is as follows:

1. Map out all the cash flows of the instrument – interest and principal.
2. Find the present value (PV) by discounting the total cash flows at each payment date using the zero or spot rate that corresponds to the time from the pricing date to the date that the cash flow is received. E.g. A payment that will be received 1.5 years from the pricing date will be discounted using the 1.5 year spot rate.
3. Sum the PV of all the cash-flows.
4. Calculate the accrued interest from the last coupon date to the pricing date and subtract this from the sum of the PVs.
5. Divide the result from #4 above by the outstanding face value of the instrument to get the clean price.

Determination of the Spot (Zero) Curve

The spot curve used in the calculation outlined above is generated by our proprietary valuation system. The Research Department uses recent market issues and market reads to construct a par yield curve each month. These par rates are uploaded into our valuation model upon approval of the Group's Market Risk Committee. Our valuation model generates the key points on the zero curves using a bootstrapping methodology and uses cubic spline interpolation to generate all the points between the key points.

For example if the 30 day, 90 day , 1 year, 2year.....20 year par points are uploaded, the system will generate the matching zero points and use cubic spline interpolation to determine the points between 30 day, 90 day , 1 year, 2year.....20 year spot rates.

The spot rates generated are entered in the respective sheets in the bond pricing model. Further cubic spline interpolation is done between the points generated using an excel Spline function to get the exact yield for the respective time to the cash-flow.

Pricing Methodology and Formulas

1. The cash-flow dates for each security are generated based on the maturity date and interest frequency. For Plain Vanilla bonds the interest or coupon payment amounts are calculated using the formula:

Face Value x Coupon Rate x Time in Years from the Last Coupon Date to the Next Coupon Date

2. The Principal payment for a Plain Vanilla bond will be equal to the face value of the bond, the total payment will be on the maturity date.
3. For Amortizing or other non standard cash-flows the cash-flow schedule provided will be used in place of the calculations outlined above.
4. After the cash-flow schedules are completed the sum of the cash-flows on each payment date is calculated. These are then discounted by multiplying by a discount factor for each payment date. The formula used for calculating the discount factors is:

$$\text{DiscountFactor} = \frac{1}{(1 + DR)^T}$$

Where:

- *T is the number of years (or fraction of a year) from the pricing date to the date of the cash-flow.*
- *DR is the discount rate which is derived by finding the spot or zero rate that corresponds to the time period T on the spot curve plus a spread if pricing a corporate bond.*

5. The total cash-flow on each payment date is then multiplied by its associated discount factor to get the present value (PV).
6. The PV's for all the cash-flows are totaled and then the accrued interest on the bond up to the day of pricing is calculated using

Face Value x Coupon Rate x Time in Years from the Last Coupon Date to the Pricing Date

7. The accrued interest is subtracted from the total PV and the result divided by the face value to give the clean price.
